

Here, I make the following argument: I demonstrate that the debate between determinism and free-will can never be fully resolved, We define determinism constructively Having a system or procedure to attribute a cause to any bit of state of the universe such that the entire universe is consistent with this cause. The last part is required to encompass “butterfly effect”-like phenomena: We know that seeing a star millions of light years away can influence human behaviour. Thus, a softer definition of determinism would be insufficient. Because causation stacks avoid infinite regress answer is satisfied by some nonreflexive cause e.g. focus on particular bit of matter or outcome and seek an explanation for its change in state that is not the change in state itself. Without this requirement, everything change in state can be trivially explained by itself

Who gets to pick the previous point in time? the procedure?

Subproblem fo testing reflexivity.

Now, suppose we have such a system of identifying cause.
